

Fossil vertebrates in the American Museum of Natural History Volume 7

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1922 Excerpt: ...(Fig. 57) the molars are becoming triconodont. The I_1 region is very marsupial-like, but the enlarged maxilla has not yet grown backward and upward above the lacrymal. In the higher cynodonts the molars vary from the shearing triconodont type of *Cynognathus* to the oval tuberculate crowns of *Diademodon* and its allies. The incisors and canines are of predatory submammalian type. The upper jaws widely overhang the lower. The mandible is submammalian in so far as the dentary is the predominant element with a wide ascending I_1 while the quadrate and articular are small and seemingly are about to be transformed into the incus and malleus. The palate is distinctly Submammalian and the atrophy of the quadrate process of the pterygoid foreshadows the subsequent reduction of that element, which is so large in all other reptiles. The lacrymal region of *Cynognathus* and *Diademodon* is very mammal-like and is in harmony with the view that the Cynodonts, as a group, are actually ancestral to the mammals. The expansion and overlap of the lumbar ribs is unique and suggests some radical changes in the musculature, possibly leading to the mammalian diaphragm and eventually to the loss of lumbar ribs and the substitution of apophyses from the centra. The shoulder girdle humerus and Pelvis foreshadow the monotreme type and in the H_1 we have the beginnings of the mammalian trochanters. In brief, the Therapsida range from relatively primitive Permian stages immediately above the pelycosaurs up to highly progressive Triassic types immediately below the mammals. It is customary to regard even

the cynoclonts as at most very remote relatives of the mammals, but it is now time to call for definite evidence in favor of this a pr...
